Calcium polystyrene sulfonate bezoar in the ileum: diagnosis and treatment with double-balloon endoscopy

An 86-year-old man, admitted for transarterial chemoembolization of a hepatoma, developed fever and acute renal failure following the procedure. He was given antibiotic therapy and oral calcium polystyrene sulfonate (30 g daily) for hyperkalemia. After 1 week, the patient developed bilious vomiting with abdominal pain. An abdominal X-ray disclosed diffuse dilatation of the small bowel (**Fig. 1**) and computed tomography was suspicious for a bezoar in the ileum along with intestinal obstruction (**Fig. 2**). A surgeon was consulted but surgical therapy was declined due to the high surgical risk. The patient received conservative medical therapy but his intestinal obstruction failed to resolve. A decision was made to carry out retrograde enteroscopy to emove the bezoar. When the ileum was entered, we found a large, tubular-shaped, firm yellowish bezoar occupying the intestinal lumen (**Fig. 3** and **Video 1**). There were also some ileal ulcers. Irrigation with water and fragmentation using a snare helped mobilize the bezoar. Multiple small brownish granules were seen after the bezoar was fragmented (**Fig. 4**) and the aspirated fluid contained resin granules. Given the endoscopic findings and the drug history of the patient, he was diagnosed as having a calcium polystyrene sulfonate resin-associated bezoar. Despite the efforts to remove the bezoar, the patient died of multiple organ failure 1 month later.

Calcium polystyrene sulfonate is an exchange resin used to treat hyperkalemia. A few cases of resin-related bezoars with intestinal obstruction have been reported [1–3]. Such bezoars most often form in critically ill infants [1–3] or in debilitated elderly patients with decreased bowel mobility and prolonged usage of the agent. The treatment of polystyrene sulfonate-related intestinal obstruction is surgery; only one case of non-surgical management has been reported [3]. The present case report documents the endoscopic findings related to resin-associated bezoar. In addition, we have found enteroscopy may be a useful tool in the treatment of intestinal obstruction resulting from the presence of such a bezoar.
