New salt forms of the antioxidant drug emoxypine (EMX, 2-ethyl-6-methyl-pyridin-3-ol) with pharmaceutically acceptable maleic (Mlt), malonic (Mln) and adipic (Adp) acids were obtained \{emoxypinium maleate, $\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{NO}^{+} \cdot \mathrm{C}_{4} \mathrm{H}_{3} \mathrm{O}_{4}{ }^{-}$, [EMX+Mlt], emoxypinium malonate, $\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{NO}^{+} \cdot \mathrm{C}_{3} \mathrm{H}_{3} \mathrm{O}_{4}{ }^{-}$, [EMX+Mln], and emoxypinium adipate, $\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{NO}^{+} \cdot \mathrm{C}_{6} \mathrm{H}_{9} \mathrm{O}_{4}^{-}$, [EMX+Adp]\} and their crystal structures determined. The molecular packing in the three EMX salts was studied by means of solid-state density functional theory (DFT), followed by QTAIMC (quantum theory of atoms in molecules and crystals) analysis. It was found that the major contribution to the packing energy comes from pyridinecarboxylate and hydroxy-carboxylate heterosynthons forming infinite onedimensional ribbons, with [EMX+Adp] additionally stabilized by hydrogenbonded $C(9)$ chains of Adp ${ }^{-}$ions. The melting processes of the [EMX+Mlt] (1:1), [EMX+Mln] (1:1) and [EMX+Adp] (1:1) salts were studied and the fusion enthalpy was found to increase with the increase of the calculated lattice energy. The dissolution process of the EMX salts in buffer ( pH 7.4 ) was also studied. It was found that the formation of binary crystals of EMX with dicarboxylic acids increases the EMX solubility by more than 30 times compared to its pure form.

## 1. Introduction

2-Ethyl-6-methylpyridin-3-ol (emoxypine, EMX) is a Russianmade drug that belongs to the class of 3-hydroxypyridines, which are structural analogues of vitamin B6. Emoxypine produces an antihypoxic, nootropic, anticonvulsant and anxiolytic action, and increases the body's ability to cope with stress (Borovikov, 2016). Since emoxypine in its pure form has a rather low solubility, it is used in the pharmaceutical industry as the hydrochloride (Emoxipine) or succinate salts (Mexidol or Mexifin). Both agents have antioxidant properties due to their ability to interact with $\mathrm{Fe}^{2+}$ ions and water-soluble radicals (e.g. the superoxide anion) and to improve the efficiency of the endogenous antioxidant system (Chesnokova et al., 2015). Mexidol is currently more popular as it is less toxic than Emoxipine (Levitskaya et al., 2016). A recently discovered salt of emoxypine with $N$-acetylglutamic acid was shown to improve biological action in rats (Yasnetsov et al., 2010, 2012). The crystal structures of known EMX salts show that emoxypine is able to form polymorphic salt forms (Chernyshev et al., 2013), as well as salts with different API/counter-ion ratios (API is an active pharmaceutical ingredient) (Lyakhov et al., 2012b).
This strategy of solubility and bioavailability enhancement by obtaining new API salts with different organic counter-ions is more and more often becoming an alternative to obtaining salts with chloride ions (Paulekuhn et al., 2007). For example,
salts of APIs with dicarboxylic acids improve the solubility of the drug compounds by a factor of dozens (Surov et al., 2015; Basavoju et al., 2006; Bruni et al., 2013). In some cases, dicarboxylic acid salts have higher solubility values than the hydrochloride salts (Manin et al., 2015). Besides, most dicarboxylic acids are considered pharmaceutically acceptable \{Orange book, 2018 [Orange Book: Approved Drug Products with Therapeutic Equivalence Evaluations (March 2018), http://www.accessdata.fda.gov/scripts/cder/ob/, US Food and Drug Administration]; Pudipeddi et al., 2002\} and potentially less harmful for the gastrointestinal tract compared to HCl due to the lower $\mathrm{p} K_{\mathrm{a}}$ of the acid (Bansal et al., 2008).

Emoxypine, EMX

Malonic acid, Mln Maleic acid, Mlt

Adipic acid, Adp

## Scheme 1

Thus, it was shown that the change of counter-ion significantly affects the in vivo performance of commercially available salt forms of EMX and this method was chosen in the search of new crystal forms with enhanced properties. First, a combined experimental and theoretical study should be conducted in order to assess the influence of the molecular and crystal structures on pharmaceutically relevant properties. There are approaches linking the solubility of pharmaceutical crystals with its melting point (Perlovich, 2014; Abramov, 2015) and theoretical lattice energy evaluated by solid-state density functional theory (DFT) (Voronin et al., 2016). The literature survey of multicomponent crystals of dicarboxylic acids with various APIs conducted in our earlier work (Manin et al., 2015) has shown the influence of the melting point and carbon chain length of the salt/cocrystal former on the potential solubility of the API. However, variations of the experimental conditions and solubility data do not allow the predictive use of named correlations for individual APIs without known reference solubility and melting point/lattice energy values, which require a preliminary screening study.

In the present work, emoxypine was reacted with a series of dicarboxylic acids, i.e. malonic (Mln), maleic (Mlt) and adipic (Adp) acids (Scheme 1), giving emoxypinium maleate, [EMX+Adp], emoxypinium malonate, [EMX+Mln], and emoxypinium adipate, [EMX+Adp]. All the salt coformers produced new crystal forms. This article focuses on the theoretical and experimental study of emoxypine salt design, and
on the physicochemical properties of the malonate, maleate and adipate salts compared to the emoxypine free base.

## 2. Experimental

### 2.1. Compounds and solvents

Emoxypine was obtained from emoxypine hydrochloride (see $\S S 1$ in the supporting information). Malonic acid (99\%), maleic acid (99\%) and adipic acid (99\%) were purchased from Acros Organics. All reagents were available commercially and were used as received without further purification.

### 2.2. Crystallization procedure

Emoxypine and dicarboxylic acid in a 1:1 molar ratio were dissolved in a methanol-acetone mixture ( $1: 1 v: v$ ) and stirred until a clear solution was obtained. The solution was kept in a fume hood at room temperature. Diffraction-quality crystals of the emoxypine salts were grown over a period of 3-4 d. The crystals obtained from the crystallization batches were dried in air before being subjected to further analysis.

### 2.3. Refinement

Crystal, data collection, and structure refinement details are summarized in Table 1. All H atoms were found in difference Fourier syntheses and refined isotropically. The powder X-ray diffraction data were recorded under ambient conditions in Bragg-Brentano geometry with a Bruker D8 Advance diffractometer with $\mathrm{Cu} K \alpha_{1}$ radiation ( $\lambda=1.5406 \AA$ ). Singlecrystal X-ray diffraction studies were performed at the Centre of Shared Equipment of IGIC RAS.

### 2.4. Differential scanning calorimetry (DSC)

The thermal analysis was carried out using a PerkinElmer DSC 4000 differential scanning calorimeter with a refrigerated cooling system (USA). The sample was heated in sealed aluminum sample holders at the rate of $10^{\circ} \mathrm{C} \mathrm{min}^{-1}$ under a nitrogen atmosphere. The unit was calibrated with indium and zinc standards. The accuracy of the weighing procedure was $\pm 0.01 \mathrm{mg}$.

### 2.5. Thermogravimetric analysis (TGA)

TGA was performed on a TG 209 F1 Iris thermomicrobalance (Netzsch, Germany). Approximately 10 mg of the sample was added to a platinum crucible. The samples were heated at a constant heating rate of $10^{\circ} \mathrm{C} \mathrm{min}^{-1}$. The samples were purged with a stream of flowing dry Ar throughout the experiment at $30 \mathrm{ml} \mathrm{min}^{-1}$.

### 2.6. Aqueous dissolution experiments

The dissolution measurements were carried out by the shake-flask method in a phosphate buffer with pH 7.4 at $25 \pm 0.1^{\circ} \mathrm{C}$. An excess amount of each sample was suspended in the respective buffer solution in Pyrex glass tubes. The amount of the drug dissolved was measured by taking aliquots of the respective media. The solid phase was removed by isothermal

filtration (Rotilabo ${ }^{\circledR}$ syringe filter, PTFE, $0.2 \mu \mathrm{~m}$ ), and the concentration was determined by suitable dilution with a Cary 50 UV-Vis spectrophotometer (Varian, Australia) at the reference wavelength. The results are stated as the average of at least three replicated experiments. The concentrations were calculated according to the established calibration curve.

### 2.7. Computational procedure

The solid-state DFT computations were performed with the CRYSTAL14 package (Dovesi et al., 2014) at the B3LYP/6$31 \mathrm{G}(\mathrm{d}, \mathrm{p})$ level of theory. The D2 dispersion correction proposed by Grimme (2006) was used both in structure optimization and in wavefunction calculation for AIM (atoms in molecules) analysis. Based on the vibrational frequency analysis (Pascale et al., 2004), all the optimized structures were found to correspond to the minimum point on the potential energy surface.

The quantum topology analysis was performed in the Topond14 (Gatti et al., 1994) software currently built into the CRYSTAL14 suite. The $(3 ;-1)$ critical points were found using a standard algorithm and the following quantities were computed in the bond-critical point: electron density, $\rho_{b}$, its Laplacian, $\nabla^{2} \rho_{b}$, and the positively defined local electronic kinetic energy $G_{b}$.

The energy of a particular noncovalent interaction, $E_{\text {int }}$, was computed using the following equation (Mata et al., 2011):

$$
\begin{equation*}
\left.E_{\text {int }}\left[\mathrm{kJ} \mathrm{~mol}^{-1}\right]=1124 G_{b} \text { [atomic units }\right] . \tag{1}
\end{equation*}
$$

The lattice energy, $E_{\text {latt }}$, was estimated as the sum of the energies of the unique intermolecular interactions in an asymmetric unit (Dominiak et al., 2012):

$$
\begin{equation*}
E_{\mathrm{latt}}=\sum_{i} \sum_{j<i} E_{\mathrm{int}, j, i} \tag{2}
\end{equation*}
$$

The calculation scheme was proved to successfully predict the energies of noncovalent interactions of various types and the sublimation enthalpies of single and multicomponent crystals (Vener et al., 2014, and references therein).

## 3. Results and discussion

According to the $\mathrm{p} K_{\mathrm{a}}$ rule, ionized acid-base complexes are observed exclusively for $\Delta \mathrm{p} K_{\mathrm{a}}>4$ and non-ionized acid-base complexes are observed exclusively for $\Delta K_{\mathrm{a}}<-1$ (CruzCabeza, 2012). In the $\Delta K_{\mathrm{a}}$ interval between 0 and 3, the probabilities of the formation of salts and cocrystals are practically equal. The difference between the $K_{\mathrm{a}}$ of emoxypine ( $\mathrm{p} K_{\mathrm{a}, 1}=6.49$ and $\mathrm{p} K_{\mathrm{a}, 2}=10.05$; Chemicalize, 2018) and the first ionization constants of malonic acid $\left(\mathrm{p} K_{\mathrm{a}, 1}=2.83\right.$ and $\mathrm{p} K_{\mathrm{a}, 2}=$ 5.69), maleic acid ( $\mathrm{p} K_{\mathrm{a}, 1}=1.90$ and $\mathrm{p} K_{\mathrm{a}, 2}=6.07$ ) and adipic acid $\left(\mathrm{p} K_{\mathrm{a}, 1}=4.43\right.$ and $\left.\mathrm{p} K_{\mathrm{a}, 2}=5.41\right)$ are negative, which indicates that salt formation is expected.

Note: $\left(^{*}\right)$ intramolecular hydrogen bond. Symmetry codes: (i) $x-\frac{1}{2},-y+1,-z+\frac{1}{2}$; (ii) $x-1, y+2, z+1$; (iii) $x-1, y, z$; (iv) $x-1, y+1, z-1$.

The literature data show that emoxypine is able to form polymorphic salts (Chernyshev et al., 2013), as well as salts with different stoichiometric ratios (Lyakhov et al., 2012b) and different ionization states with dicarboxylic acids (Lyakhov et al., 2012a). Therefore, special attention was paid to varying the experimental conditions in an attempt to discover possible multiple crystal forms for one binary system.

The screening was conducted using the method of slow crystallization from solution. The solvents were methanol, ethanol, acetonitrile, acetone, tetrahydrofuran, ethyl acetate and mixtures of these solvents. The screening experiments yielded three novel crystal forms of EMX with maleic, malonic and adipic acids (see Table S1 in the supporting information).

### 3.1. Crystal structures of the salts

An emoxypine molecule contains two sites available for hydrogen bonding, namely a hydroxy group and a pyridine ring. The core of the molecule is essentially planar; however, substitution of the ortho positions of the N atom with alkyl groups prevents the formation of planar synthons, such as a common $R_{2}^{2}(9)$ acid-pyridine heterosynthon. Since the alkyl H
atoms are located out of the main plane of the EMX molecule, the coordinated carboxyl groups are not parallel to the EMX plane, which leads to twisted acid-pyridine synthons. Since the number of hydrogen-bond-acceptor sites in the EMX-dicarboxylic acid system exceeds the number of hydrogen-bond donors (five against three), $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts are also likely to be observed to saturate the remaining acceptors according to Etter's rules (Etter, 1990).

The crystallographic data for the emoxypine salts are summarized in Table 1, and the asymmetric units of the EMX salts with displacement ellipsoids, along with the packing arrangements of the salts, are shown in Figs. 1-3. The singlecrystal X-ray diffraction data confirm the protonation of the pyridine ring of EMX by acid groups of the salt formers, as evidenced by the proton location and bond-length distribution (Table 2).

The [EMX+Mlt] salt crystallizes in the orthorhombic Pccn space group. The asymmetric unit of [EMX+Mlt] includes one emoxypine cation and one maleate anion with a strong intraion hydrogen bond (Fig. 1a). The EMX and Mlt ions are held together by hydrogen bonds of two types, i.e. a charge-assisted $\mathrm{N}^{+}-\mathrm{H} \cdots \mathrm{O}$ and a neutral $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond, leading

(a)

(b)

Figure 1
(a) The hydrogen-bonded supramolecular asymmetric unit in the crystal structure of [EMX+MIt] (displacement ellipsoids are drawn at the $50 \%$ probability level) and (b) a molecular packing projection for [EMX+MIt].
to the formation of infinite chains along the $a$ axis. The chains, in their turn, are held together by weaker intermolecular interactions (Fig. 1b).

The $[\mathrm{EMX}+\mathrm{Mln}]$ salt crystallizes in the triclinic $P \overline{1}$ space group. The asymmetric unit of [EMX+Mln] includes two emoxypine cations and two hydrogen malonate anions (Fig. 2a). Similar to the $[\mathrm{EMX}+\mathrm{Mlt}]$ crystal, the anion adopts a cyclic conformation with an intra-ion hydrogen bond. The EMX and Mln ions form an infinite chain, in which each of the two symmetrically independent ions is held together by one $\mathrm{N}^{+}-\mathrm{H} \cdots \mathrm{O}$ and one $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bond (Fig. 2b). It is interesting to note that alternation of the orientation of the anions is observed in chains of the emoxypine malonate and maleate salts, while the orientation of the EMX ions changes only in [EMX+Mlt]. Neighbouring chains of the hydrogenbonded molecules lie above each other and form tunnel-like structures. The chains are equidistant from each other and are held together by $\pi-\pi$ interactions (Fig. $2 c$ ).

The [EMX+Adp] salt crystallizes into the triclinic $P \overline{1}$ space group. The asymmetric unit of [EMX+Adp] contains one emoxypine cation and one adipate anion (Fig. 3a). The EMX molecules are linked with neighbouring molecules of adipic acid by $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}^{-}$and $\mathrm{N}^{+}-\mathrm{H} \cdots \mathrm{O}$ charge-assisted hydrogen bonds and form infinite chains. These chains are linked with each other via the adipic acid molecules by $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds (Fig. 3b). The planes formed in this way lie at a distance of $3.18 \AA$ from each other (Fig. 3c).

### 3.2. Pattern of intermolecular interactions

In order to achieve a better understanding of the driving forces responsible for emoxypine salt formation, the mol-

Note: $\left({ }^{*}\right)$ all the energies are given in $\mathrm{kJ} \mathrm{mol}^{-1}$ and as a $\%$ of the $E_{\text {latt }}$ value
ecular packing in the three EMX salts was studied by means of solid-state DFT, followed by QTAIMC analysis. The Bader analysis of periodic electron density allowed us to arrange the main hydrogen-bonding motifs by energy.

In the $[\mathrm{EMX}+\mathrm{Mlt}]$ crystal, the extra strong short $(\mathrm{O} \cdots \mathrm{O}=$ $2.43 \AA$ ) intramolecular $\mathrm{O} 11-\mathrm{H} 11 \cdots \mathrm{O}^{-}$hydrogen bond (Steiner, 2002) in the Mlt ${ }^{-}$anion was found to be the strongest noncovalent interaction (Table 2, and Table S2 of the supporting information). An unusually short $\mathrm{O} \cdots \mathrm{O}$ distance and a high $\rho_{b}$ value at the $(3 ;-1)$ point indicated the partially covalent nature of this interaction (Gatti, 2005).

Due to the cyclic conformation, the Mlt and Mln ions do not form any strong bonds with each other, and acid-acid interactions make up less than $10 \%$ of the lattice energy (Table 3). Thus, the structure is mainly stabilized by EMX-acid and EMX-EMX interactions.

If the conformational change leading to reduction of symmetry in $[\mathrm{EMX}+\mathrm{Mln}]$ is not taken into account, both

Figure 3
(a) The asymmetric unit in the [EMX+Adp] crystal (displacement ellipsoids are drawn at the $50 \%$ probability level), consisting of two EMX molecules and an adipate ion. (b) The $R_{6}^{6}(38)$ hydrogen-bonded ring motif formed by two EMX molecules and four adipate ions in the crystal, held together by charge-assisted $\mathrm{N}^{+}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}^{-}$hydrogen bonds. (c) A molecular packing projection for [EMX+Adp].
crystals show packing similarities reflected by QTAIMC results. The pattern of noncovalent interactions in the maleate and malonate salts is hydrogen-bonded EMX-acid chains held together by weaker interactions. The O atoms are coordinated within heterosynthons in $[\mathrm{EMX}+\mathrm{Mlt}]$ in a fashion similar to [EMX+Adp], with three additional $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts for the acid-pyridine hydrogen bond and a stronger single $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contact for the hydroxy-acid bond (Fig. 4). The total energy gains within these synthons are similar: $65 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for hy-droxy-carboxylate and $58 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for pyridine-carboxylate.

Figure 4
Part of the crystal lattice with noncovalent interactions in the [EMX+MIt] salt. Hydrogen bonds are shown as blue lines and the main $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts are shown as green lines. The numbers represent the energies of particular noncovalent interactions in $\mathrm{kJ} \mathrm{mol}^{-1}$, with red numbers corresponding to intramolecular contacts.

Taken together, these interactions within the chain contribute more than $50 \%$ to the crystal lattice energy.

The ethyl-group orientation within the chain alternates due to the twofold roto-translational symmetry. Due to the wavelike shape of the parallel layers shown in Fig. 1(b) and a relatively small (about $3.5 \AA$ ) interlayer distance, $\pi$-stacking interactions are likely to be observed in the studied system. The total energy of the interactions within the stack is $32 \mathrm{~kJ} \mathrm{~mol}^{-1}$, or $14 \%$ of $E_{\text {latt }}$, of which $18 \mathrm{~kJ} \mathrm{~mol}^{-1}$ comes from $\mathrm{C} 7 / \mathrm{C} 8-\mathrm{H} \cdots \mathrm{O}$ contacts between the nearest chains and $27 \mathrm{~kJ} \mathrm{~mol}^{-1}$ from the $\pi$-stacking interactions between the nonH atoms. An additional $22 \mathrm{~kJ} \mathrm{~mol}^{-1}$ comes from the $\mathrm{H} \cdots \mathrm{H}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{C}$ contacts of alkyl fragments with the surrounding atoms.

A number of $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{H} \cdots \mathrm{H}$ contacts between the EMX and Mlt molecules combine the adjacent stacks of chains into corrugated sheets, which leads to a $36 \mathrm{~kJ} \mathrm{~mol}^{-1}$ gain in the stabilization energy. The relatively strong $\mathrm{C} 8-\mathrm{H} 82 \cdots \mathrm{O} 13$ ( $8.5 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ) and $\mathrm{C} 6-\mathrm{H} 61 \cdots \mathrm{O} 14$ contact $\left(6.7 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$, and the supporting $\mathrm{H} \cdots \mathrm{H}$ interactions distort the parallel orientation of adjacent hydroxy-acid dimers. The total lattice energy of $[\mathrm{EMX}+\mathrm{Mlt}]$ evaluated using equation 2 is $226.3 \mathrm{~kJ} \mathrm{~mol}^{-1}$.

The asymmetric unit in [EMX+Mln] contains two EMX molecules with a nearly identical conformation, differing only in torsion angle $\tau$ (see Fig. 5) and two molecules of Mln are rotated at about $180^{\circ}$ relative to each other. While all the non-H atoms of one $\mathrm{Mln}^{-}$ion (referred to as $\mathrm{Mln}-A$ ) are located in a single plane, the geometry of the second anion (Mln-B) is far from planar (the angle between the mean planes $\mathrm{C} 42-\mathrm{C} 41-\mathrm{O} 41-\mathrm{O} 42$ and $\mathrm{C} 42-\mathrm{C} 43-\mathrm{O} 43-\mathrm{O} 44$ is $163^{\circ}$ ). As shown elsewhere (Bauer et al., 2001; Khodov et al., 2014, 2016; Surov et al., 2016), the distorted conformation of the molecule in the condensed phase is an indicator of possible strong interactions involving the displaced atoms, as additional stabilization energy is required to overcome the conformational penalty. In our case, the energy of the hydrogen bonds (including an intramolecular one) and the

Figure 5
Noncovalent interactions revealed by QTAIMC within the chains of emoxypine and malonate ions in the [EMX+MIn] salt, with the hydrogen bonds shown as blue lines and the main $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts shown as green lines. The numbers display the energies of particular noncovalent interactions in $\mathrm{kJ} \mathrm{mol}^{-1}$, with red numbers corresponding to the intramolecular contacts.
$\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts accepted by the O atoms of a single Mln molecule exceeds $100 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (Fig. S1 in the supporting information).

Of the two conformationally different EMX molecules, EMX- $B$, with $\tau(\mathrm{N} 1-\mathrm{C} 1-\mathrm{C} 6-\mathrm{C} 7)=92.6^{\circ}$, participates in a unique intramolecular $\mathrm{C} 28-\mathrm{H} 282 \cdots \mathrm{O} 2$ contact with an energy of $9.6 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (Fig. 5). Since this interaction is absent in the [EMX+Mlt] crystal, where the torsion $\tau$ in EMX is only $3^{\circ}$ higher, one can suppose the range ( $93-95^{\circ}$ ) to be critical for intramolecular $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen-bond formation.

The strongest interactions in the [EMX+Mln] crystal are two intramolecular hydrogen bonds in conformationally different $\mathrm{Mln}^{-}$ions. Compared to [EMX+Mlt], these interactions are weaker, with the $\mathrm{O} \cdots \mathrm{O}$ distance equal to $2.44 \AA$ and $\rho_{b}=0.080-0.086$ a.u.; however, they can also be classified as electron-sharing partially covalent interactions (Table 2, and Table S3 in the supporting information).

The energies of synthon interactions are slightly different in conformationally different emoxypine-malonate pairs. For the hydroxy-carboxylate synthon, the total energy is $64 \mathrm{~kJ} \mathrm{~mol}^{-1}$ in the EMX- $A-\mathrm{Mln}-A$ dimer and $63 \mathrm{~kJ} \mathrm{~mol}^{-1}$ in the EMX- $B-$ Mln- $B$ dimer. Both pyridyl-carboxylate synthons in EMXMln are additionally stabilized by two additional $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts, with the ethyl group left free to coordinate the molecules of adjacent chains (Fig. 5). The synthon energies in

Figure 6
Part of the crystal lattice showing hydrogen bonds (blue lines) and the main $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts (green lines) in the $[\mathrm{EMX}+\mathrm{Adp}$ ] salt. The numbers represent the energies of particular noncovalent interactions in $\mathrm{kJ} \mathrm{mol}^{-1}$.
the EMX- $A-$ Mln- $B$ and EMX- $B-$ Mln- $A$ dimers are 47 and $49 \mathrm{~kJ} \mathrm{~mol}^{-1}$, respectively. Note that a weaker hydrogen bond in the considered crystals is always accompanied by stronger $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds, partially compensating for the difference in synthon energies. Taken together, the interactions within the heterosynthon-bonded chain comprise $55 \%$ of all the noncovalent interaction energy in the crystal. Table S3 (see supporting information) contains a detailed description of the metric and quantum-topological properties at the bond critical points.

The block-like packing of parallel hydrogen-bonded chains shown in Fig. 2(c) allows a comparison of the stabilization energy between the chains with different orientations of the ethyl groups (i.e. facing towards each other or in opposite directions). It has been found that the stabilization energy of the interactions between the ethyl fragment and its surroundings is compensated by a weakening of other noncovalent interactions, leading to nearly equal contributions to $E_{\text {latt }}$.

The total contributions of EMX- $A$, EMX- $B$, Mln- $A$ and Mln- $B$ to $E_{\text {latt }}$ are given in Table S 5 (see supporting information). The bent conformation of Mln- $B$ is preferable in terms of packing, as it brings an additional $6 \mathrm{~kJ} \mathrm{~mol}^{-1}$ into the lattice energy. A simple single-point calculation of isolated molecules of Mln- $A$ and Mln- $B$ has revealed that this value is higher than the conformational energy required for bending the malonate ion. The details of this calculation are presented in S3 (see supporting information).

The strongest noncovalent interaction in the [EMX+Adp] crystal, with $E_{\mathrm{int}}=72.5 \mathrm{~kJ} \mathrm{~mol}^{-1}$, is the $\mathrm{O} 11-\mathrm{H} 11 \cdots \mathrm{O} 13$ hydrogen bond linking the $\mathrm{Adp}^{-}$ions into infinite $C(9)$ chains along the crystallographic $a$ axis. The formation of infinite chains is common in 1:1 salts of dicarboxylic acid, as was reported elsewhere (Surov et al., 2015, 2016).

Each $\mathrm{EMX}^{+}$ion is involved in two hydrogen bonds with Adp ${ }^{-}$, where it acts as a donor. The hydroxy-carboxylate bond is shorter than the pyridinium-carboxylic bond and has a higher $E_{\text {int }}$ value ( 60 versus $36 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ). The value of $\rho_{b}=$ 0.72 a.u. indicates that the $\mathrm{O} 4-\mathrm{H} 4 \cdots \mathrm{O} 5$ hydrogen bond is located in the border region between pure closed-shell interactions and partially covalent bonds. Unlike crystals of pure

| :--- | :--- | :--- | :--- |
| [EMX+Mln] (1:1) | $124.8 \pm 0.2$ | $27.4 \pm 0.6$ | 135.60 |
| [EMX+Mlt] $(1: 1)$ | $133.2 \pm 0.3$ | $34.8 \pm 0.6$ | 142.70 |
| [EMX+Adp] (1:1) | $115.8 \pm 0.5$ | $53.5 \pm 1.1$ | 151.92 |
| EMX | 168.81 | 16.6 | - |

Note: (a) for the salts, the values correspond to a mole of molecules in the asymmetric unit.

EMX, both molecules involved in $\mathrm{O}-\mathrm{H} \cdots X$ hydrogen bonding are located in the same plane. The possible reason for this is the $\mathrm{C} 3-\mathrm{H} 3 \cdots \mathrm{O} 13$ contact with $E_{\text {int }}$ equal to $13 \mathrm{~kJ} \mathrm{~mol}^{-1}$, which stabilizes the hydroxy-carboxylate synthon, making it planar (Fig. 6). The third strongest hydrogen bond in the crystal, with an energy of $36 \mathrm{~kJ} \mathrm{~mol}^{-1}$, builds the acid-pyridine synthon. This interaction belongs to the 'closed-shell' type, with almost no electron-pair sharing. Surprisingly, the charge-assisted acid-pyridine synthon, with three additional $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts, contributes only $57 \mathrm{~kJ} \mathrm{~mol}^{-1}$ to the lattice energy, while the hydroxy-acid synthon brings $73 \mathrm{~kJ} \mathrm{~mol}^{-1}$. Weaker $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts between EMX-EMX and EMX-Adp molecules complete the two-dimensional (2D) hydrogen-bonded sheet. The O atoms are coordinated within heterosynthons in [EMX + Adp] in a fashion similar to that in $[\mathrm{EMX}+\mathrm{Mlt}]$, with three additional $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts for an acid-pyridine hydrogen bond and a stronger single $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contact for a hydroxy-acid hydrogen bond.

A further quantum-topological analysis has revealed a number of weak contacts between adjacent 2D sheets, with the total energy equal to $93 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (about $30 \%$ of the total $E_{\text {latt }}$ value). Among them, the largest contribution comes from nine $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{N}$ interactions between the alkyl fragments of the Adp and EMX molecules and free O - and N atom acceptors, with an average energy of $5 \mathrm{~kJ} \mathrm{~mol}^{-1}$. Other contributions (about $16 \mathrm{~kJ} \mathrm{~mol}^{-1}$ or $5 \%$ each) include phenyl-

phenyl and phenyl-carboxyl stacking interactions, and close $\mathrm{H} \cdots \mathrm{H}$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{C}$ contacts. A summary of the found bond critical points and metric parameters of the corresponding interactions is presented in Table S 4 (see supporting information). The formation of close contacts with the out-of-plane ethyl fragment causes an increase in the interlayer distances in the areas close to the ethyl fragments, leading to a deviation of the layer from planarity.

In contrast to the other two salts studied, the acid-acid interactions in [EMX+Adp] contribute $30 \%$ of the lattice energy due to the $\mathrm{O} 11-\mathrm{H} 11 \cdots \mathrm{O} 13$ hydrogen bond and side-to-side $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ contacts listed in Table S 4 (see supporting information). This packing type is more robust than the chainlike molecular arrangement, as the total interaction energies within the EMX-Adp chain and between the chains are comparable.

Due to strong hydrogen bonds between the anions, [EMX+Adp] has the highest lattice energy of all the studied crystals, i.e. $316 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (Table 3). The main bonding patterns, lattice energies and contributions of different types of noncovalent interactions in [EMX+Mlt] and [EMX+Mln] are similar, revealing the packing similarity between these crystals. Therefore, one could expect them to exhibit similar physicochemical properties.

### 3.3. Thermal analysis

The thermal stability of the emoxypine salts has been evaluated by the DSC (differential scanning calorimetry) method. The DSC results for the salts and pure emoxypine are shown in Fig. 7, and the thermal data are given in Table 4. As Table 4 indicates, the melting temperatures for all of the studied salts are located below the melting temperatures of the respective pure components. The [EMX+Adp] (1:1) salt has the lowest melting temperature $\left(115.8^{\circ} \mathrm{C}\right)$, while the largest thermal stability $\left(133.2^{\circ} \mathrm{C}\right)$ is observed in [EMX+Mlt] (1:1).

If the main contribution to $\Delta G$ of the cocrystal melting process is made by the enthalpy component, we can see a correlation between the temperature $\left[T_{\text {fus }}\right.$ (salt)] and the

Table 5
Solubilities at $25^{\circ} \mathrm{C}$ for EMX salts and pure EMX in pH 7.4 media.

|  | Solubility $\left(\mathrm{mol} \mathrm{l}^{-1}\right)$ | Solid phase recovered after <br> solubility experiment ${ }^{a}$ |
| :--- | :--- | :--- |
| $[\mathrm{EMX}+\mathrm{Mln}](1: 1)$ | $1.8 \pm 0.1$ | amorphous |
| [EMX+Mlt] (1:1) | $1.7 \pm 0.1$ | [EMX+Mlt] |
| [EMX+Adp] (1:1) | $0.38 \pm 0.05$ | [EMX+Adp] |
| EMX | $0.047 \pm 0.01$ | EMX |

Note: (a) the residual materials were identified by DSC and PXRD analyses (Fig. S2-S5 in the supporting information).
melting enthalpy ( $\Delta H_{\text {fus }}^{T}$ ) (Perlovich et al., 2013; Perlovich, 2015). In our case, such a correlation is not observed, which allows us to suppose the dominance of the entropy component in the melting process.

It should be mentioned that the melting enthalpy values of the studied salts correlate quantitatively with the crystal lattice energies (see §3.2).

### 3.4. Aqueous solubility

The main aim of obtaining new cocrystals and salts of an API is to increase solubility. That is why we have studied the emoxypine dissolution processes. The solubility of emoxypine and its salts was examined in a phosphate buffer with pH 7.4 at $25^{\circ} \mathrm{C}$. The results of the dissolution experiments for pure EMX and its salts are summarized in Table 5. Fig. 8 shows the dissolution profiles of the salts and EMX in pH 7.4 media.

The solubility of EMX in the pH 7.4 buffer solution is low, reaching $0.047 \pm 0.01 \mathrm{~mol} \mathrm{l}^{-1}$. As Fig. 8 shows, formation of salts with dicarboxylic acids leads to a significant increase in EMX solubility. The EMX solubility in EMX adipate becomes 8 times higher, while the salts with maleic and malonic acids enhance emoxypine solubility by over 36 times.

It should be said that a solubility increase correlates with the data of the calculated salt crystal lattice energies. The salt of adipic acid with a low crystal lattice energy has the lowest solubility, whereas the salts with maleic and malonic acids with comparable energies increase emoxypine solubility an equal number of times. Besides, the obtained solubility data of the salts confirm the correlation that we established between the carbon chain length of the salts and cocrystals and their solubility parameters. The increased number of carbons in the chain narrows the interval of potential API solubility growth (Manin et al., 2015).

Dissolution profiles for salts and cocrystals usually demonstrate a 'spring and parachute' behaviour (Thakuria et al., 2013; Babu \& Nangia, 2011). According to this concept, the 'spring' effect is caused by fast dissociation of the cocrystal to form thermodynamically unstable amorphous-like species of a poorly soluble drug, whereas the longer-term 'parachute' effect occurs because of slow crystallization of this amorphous material to stable crystalline phases in the presence of a wellsoluble component. However, the dissolution profiles of EMX salts do not have pronounced 'spring' effects, which are explained by the high stability of the salts in solution. In fact, analysis of the solubility in the bottom phases after the
experiment has shown that the [EMX+Mlt] and [EMX+Adp] salts retain the salt form and do not dissociate into individual components.

## 4. Conclusions

Three new salts of emoxypine with aliphatic dicarboxylic acids (maleic, malonic and adipic acids) were obtained and analyzed by experimental (X-ray and DSC) and theoretical (DFT computations) techniques. Despite the fact that emoxypine is able to form polymorphic salts, as well as salts with different stoichiometric ratios, we found only the anhydrous forms of the considered salts in which the components were in a $1: 1$ stoichiometric ratio. Alternation of the orientation of the anions was observed in the chains of the emoxypine malonate and maleate salts, while the orientation of the EMX ions changes only in [EMX+Mlt]. It was found that the absence of an intramolecular hydrogen bond in the adipate anion led to a higher lattice energy and, consequently, lower solubility and higher fusion enthalpy. Thermal analysis of the EMX salts showed that the values of the melting enthalpies of the studied salts correlated quantitatively with the values of the crystal lattice energies. The solubility of the salts was measured in a pharmaceutically relevant buffer solution with pH 7.4. The [EMX+Mlt], [EMX+Mln] and [EMX+Adp] salts demonstrated a 36-, 38- and 8 -fold solubility improvement, respectively, relative to pure EMX. Further biopharmaceutical studies are required to investigate and to compare the behaviour of the salts in vivo.

2-Ethyl-3-hydroxy-6-methylpyridin-1-ium 3-carboxyprop-2-enoate (I)

## Crystal data

$\mathrm{C}_{8} \mathrm{H}_{12} \mathrm{NO}^{+} \cdot \mathrm{C}_{4} \mathrm{H}_{3} \mathrm{O}_{4}^{-}$
$M_{r}=253.25$
Orthorhombic, Pccn
Hall symbol: -P 2ab 2ac
$a=26.571$ (3) $\AA$
$b=6.9074$ (8) $\AA$
$c=13.5152(16) \AA$
$V=2480.6(5) \AA^{3}$
$Z=8$

## Data collection

Bruker SMART APEXII
diffractometer
Radiation source: fine-focus sealed tube
Graphite monochromator
$\omega$ scans
Absorption correction: multi-scan
(SADABS; Bruker, 2008)
$T_{\text {min }}=0.964, T_{\text {max }}=0.979$
$F(000)=1072$
$D_{\mathrm{x}}=1.356 \mathrm{Mg} \mathrm{m}^{-3}$
Mo $K \alpha$ radiation, $\lambda=0.71073 \AA$
Cell parameters from 6269 reflections
$\theta=3.0-30.1^{\circ}$
$\mu=0.11 \mathrm{~mm}^{-1}$
$T=150 \mathrm{~K}$
Parallelepiped, colourless
$0.35 \times 0.20 \times 0.20 \mathrm{~mm}$

19445 measured reflections
2713 independent reflections
2282 reflections with $I>2 \sigma(I)$
$R_{\text {int }}=0.026$
$\theta_{\text {max }}=27.0^{\circ}, \theta_{\text {min }}=3.0^{\circ}$
$h=-33 \rightarrow 33$
$k=-8 \rightarrow 8$
$l=-17 \rightarrow 16$

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.037$
$w R\left(F^{2}\right)=0.101$
$S=1.04$
2713 reflections
223 parameters
0 restraints
Primary atom site location: structure-invariant direct methods

Secondary atom site location: difference Fourier map
Hydrogen site location: difference Fourier map
All H-atom parameters refined
$w=1 /\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0506 P)^{2}+0.7672 P\right]$
where $P=\left(F_{\mathrm{o}}^{2}+2 F_{\mathrm{c}}^{2}\right) / 3$
$(\Delta / \sigma)_{\text {max }}<0.001$
$\Delta \rho_{\max }=0.23$ e $\AA^{-3}$
$\Delta \rho_{\text {min }}=-0.19$ e $\AA^{-3}$

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
Refinement. Refinement of $\mathrm{F}^{2}$ against ALL reflections. The weighted R -factor wR and goodness of fit S are based on $\mathrm{F}^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>2 \operatorname{sigma}\left(\mathrm{~F}^{2}\right)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on $\mathrm{F}^{2}$ are statistically about twice as large as those based on F , and R - factors based on ALL data will be even larger.

Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters ( $\AA^{2}$ )

All H -atom parameters refined
$w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}{ }^{2}\right)+(0.0632 P)^{2}+0.1019 P\right]$
where $P=\left(F_{\mathrm{o}}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3$
$(\Delta / \sigma)_{\text {max }}<0.001$
$\Delta \rho_{\text {max }}=0.33$ e $\AA^{-3}$
$\Delta \rho_{\text {min }}=-0.23$ e $\AA^{-3}$

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
Refinement. Refinement of $\mathrm{F}^{2}$ against ALL reflections. The weighted R -factor wR and goodness of fit S are based on $\mathrm{F}^{2}$, conventional R-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>2$ sigma $\left(F^{2}\right)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on $\mathrm{F}^{2}$ are statistically about twice as large as those based on F , and R - factors based on ALL data will be even larger.

Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters ( $\hat{A}^{2}$ )

$V=714.9(2) \AA^{3}$

## Data collection

## Bruker SMART APEXII

diffractometer
Radiation source: fine-focus sealed tube
Graphite monochromator
$\omega$ scans
Absorption correction: multi-scan
(SADABS; Bruker, 2008)
$T_{\min }=0.957, T_{\max }=0.971$

## Refinement

Refinement on $F^{2}$
Least-squares matrix: full
$R\left[F^{2}>2 \sigma\left(F^{2}\right)\right]=0.041$
$w R\left(F^{2}\right)=0.114$
$S=1.05$
3122 reflections
265 parameters
0 restraints
Primary atom site location: structure-invariant direct methods
$Z=2$
$F(000)=304$
$D_{\mathrm{x}}=1.316 \mathrm{Mg} \mathrm{m}^{-3}$
Mo $K \alpha$ radiation, $\lambda=0.71073 \AA$
Cell parameters from 2982 reflections
$\theta=2.4-30.3^{\circ}$
$\mu=0.10 \mathrm{~mm}^{-1}$
$T=150 \mathrm{~K}$
Prism, colourless
$0.45 \times 0.40 \times 0.30 \mathrm{~mm}$

6841 measured reflections
3122 independent reflections
2569 reflections with $I>2 \sigma(I)$
$R_{\text {int }}=0.021$
$\theta_{\text {max }}=27.0^{\circ}, \theta_{\text {min }}=2.2^{\circ}$
$h=-11 \rightarrow 11$
$k=-11 \rightarrow 11$
$l=-12 \rightarrow 12$

Secondary atom site location: difference Fourier map
Hydrogen site location: difference Fourier map
All H -atom parameters refined
$w=1 /\left[\sigma^{2}\left(F_{0}^{2}\right)+(0.0678 P)^{2}+0.0968 P\right]$
where $P=\left(F_{0}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3$
$(\Delta / \sigma)_{\text {max }}<0.001$
$\Delta \rho_{\text {max }}=0.26$ e $\AA^{-3}$
$\Delta \rho_{\text {min }}=-0.22$ e $\AA^{-3}$

## Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
Refinement. Refinement of $\mathrm{F}^{2}$ against ALL reflections. The weighted R -factor wR and goodness of fit S are based on $\mathrm{F}^{2}$, conventional $R$-factors $R$ are based on $F$, with $F$ set to zero for negative $F^{2}$. The threshold expression of $F^{2}>2 \operatorname{sigma}\left(\mathrm{~F}^{2}\right)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on $\mathrm{F}^{2}$ are statistically about twice as large as those based on F , and R - factors based on ALL data will be even larger.

Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters ( $\hat{A}^{2}$ )
